

Maps illustrating multiple scales of the Oregon UWIN project (1) Willamette River basin, (2) Chicken Creek watershed, and (3) Sherwood Urban Reserve.

Scale	Area (ha)	Model	Indicators
Willamette River Basin	2,972,800	Envision	Water supply, demand vol.
Chicken Creek Watershed	4,150	OUIWInvision; Species-Habitat	Min., Max flows Biodiversity
Sherwood UR	492	SWMM	Area of GI, peak flows

Title: Innovations in Urban Water Systems

Research Problem: To what extent can innovative water system design and management mitigate impacts of future change?

Methods: We used a stakeholder-guided process to develop three alternative future scenarios for the Willamette River Basin (WRB) that explore the effects of climate change, population growth, and human responses to these future challenges. Although the project focus is on impacts to water systems, we implemented scenario designs by envisioning landscape change across the WRB at three scales. The impacts of landscape change can thus be assessed for other systems. The scenarios combine two rates of climate and population change with three policy and management responses.

Drivers	Early Adopter (IWF)	Late-Adopter (CC)	Non-Adopter (SR)
Human Response	"One-water" integrated mgmt.	Current policies retained	Water infrastructure stressed
Climate	4.2°C increase in MAT; less snow	2.5 °C increase in MAT; less snow	4.2°C increase in MAT; less snow
Population	6.2 million	4.5 million	6.2 million

Modeling Across Scales

The relative impacts of climate change and population growth vary with scale, and different modeling approaches are needed to quantify impacts at each scale. The Stormwater Management Model (SWMM) is the standard model used to assess performance of stormwater infrastructure at the neighborhood scale, often using sub-hourly time steps at a spatial grain of ~ 5 hectares. This temporal and spatial resolution is not feasible for larger spatial extents. However, basin-scale climate impacts (e.g., wildfire, reservoir storage) are important to water management in cities throughout the basin. The Envision model was most appropriate to evaluate climate impacts. Stakeholders were most interested in modeling at the scale of Chicken Creek, in order to compare the impacts of nature-based solutions in exurban areas of the watershed to impacts of neighborhood scale design. For this scale, we used a version of the Envision model with SWMM incorporated into the model, a daily time step, and a spatial grain of ~ 80 ha.

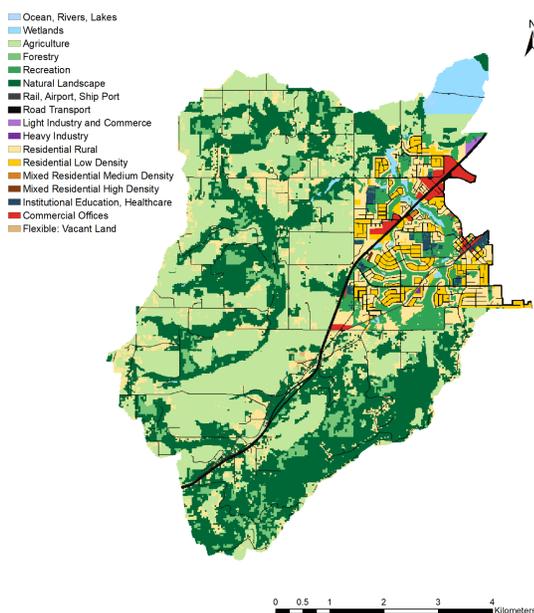

Requirements

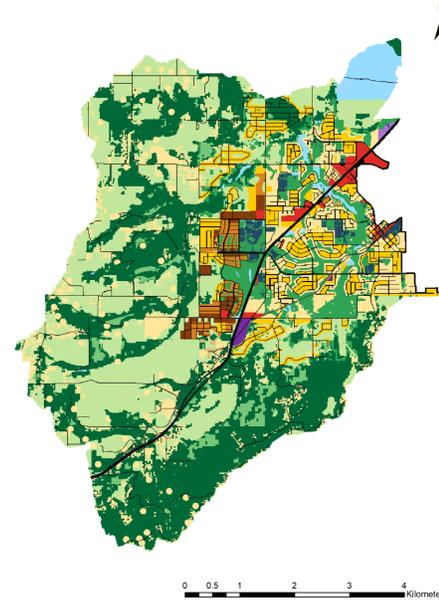

- Population Growth: Increases by the decade 2050-2060
- Urban development: Within areas surrounding major cities
- Climate Change: Increases in temperature and precipitation
- Water Storage: New claims made for stored water
- Institutions: Policy responses to mitigate negative impacts

Innovations

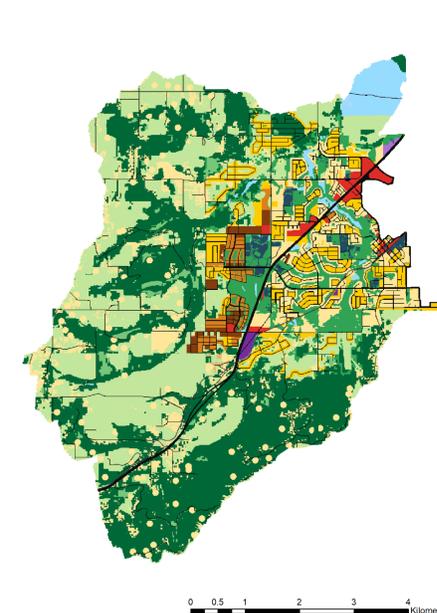

1. AGR 2035/2050 [new] Forest fuel reduction
2. GRN 2035 [1] Resilient landscape infrastructure
3. GRN 2035/2050 [8] Ecosystem services of green infrastructure
4. GRN 2035/2050 [10] Green urban streets
5. GRN 2035 [13] Regaining the riparian ecosystem
6. INS 2035/2050 [new] Agencies and institutions collaborate more frequently and water sharing agreements more common
7. MIX 2035 [14] Sustainable neighborhood pattern and design
8. WAT 2035 [8] Bioretention
9. WAT 2035/2050 [3] Agricultural water conservation and best management practices
10. WAT 2035/2050 [new] Increased water reuse

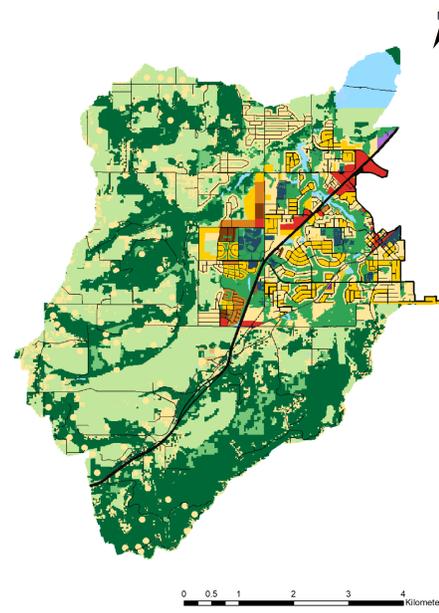

Existing situation: 2020

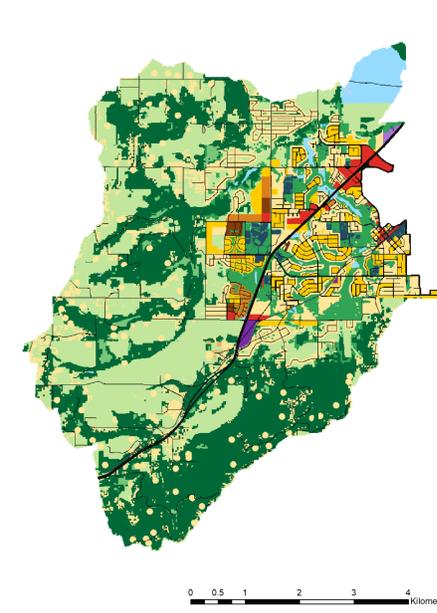

Early adopter: 2035

Early adopter: 2050

Late adopter: 2035

Late adopter: 2050

"One Water"

"One Water" approaches promote integrating water management across drinking water, wastewater, stormwater and natural hydrologic systems. "One water goals" include the following:

- Provide reliable, secure, clean water supplies
- Provide resiliency to climate and economic changes
- Minimize environmental pollution
- Promote long-term sustainability, equity, and prosperity
- Contribute to a livable city
- Protect human health
- Provide flood protection

We focused on watersheds and urban areas in the Willamette River Basin, OR to ask "How might integrated urban water management manifest across the landscape?" and, "To what extent can "One Water" approaches mitigate impacts of climate change and population growth?"

Early adopter scenario

The Oregon Urban Water Innovation Network Integrated Water Future ca. 2060 Scenario Narrative

As defined by stakeholders advising the project, the central organizing principle of the Integrated Water Future is, "Water quality and quantity are managed at the watershed scale" in ways that anticipate and respond to challenges of future change. Policy objectives for urban development and the design and operation of water management systems include conservation and restoration of natural hydrological resources in the watershed to the maximum extent plausible.

Development	Watershed Protection	Conservation & Water Re-use	Green Infrastructure
5869 new dwellings; focus on high density development	Agency partnerships expand; riparian area & wetlands protected	Broad adoption of high efficiency practices; moderate graywater & stormwater reuse	Bioretention, swales, buffers, green blvds., green roofs; 55 ha GI in Sherwood Urban Reserve

Late adopter scenario

The Oregon Urban Water Innovation Network Current Course ca. 2060 Scenario Narrative

The Late Adopter (OUWIN Current Course, CC) scenario assumes that current trends continue in population growth, climate change, and policy. Stakeholders advising the project defined the central organizing principle of the Current Course alternative future as: "Current regulatory regimes concerning water management and land use remain in effect." Existing trends in drinking water supply and quality, stormwater and wastewater facility development, monitoring and maintenance continue over time.

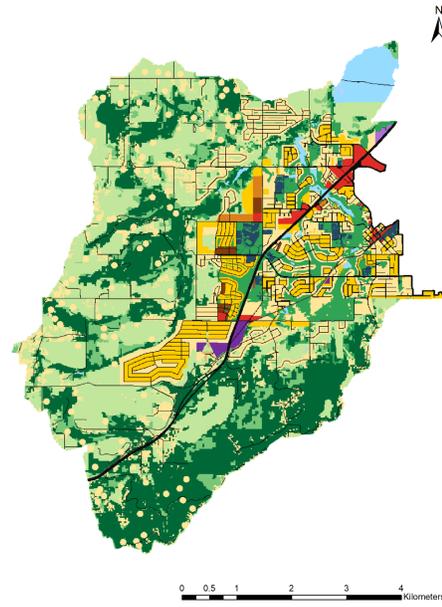

Development	Watershed Protection	Conservation & Water Re-use	Green Infrastructure
3620 new dwellings in urban reserve; mix of moderate & high density	Existing agency partnerships remain; high priority riparian areas protected	Moderate adoption of high efficiency practices; little water reuse	Bioretention areas, swales, moderate riparian buffers; 32 ha GI in Sherwood Urban Reserve

Examples of Innovations in Scenarios

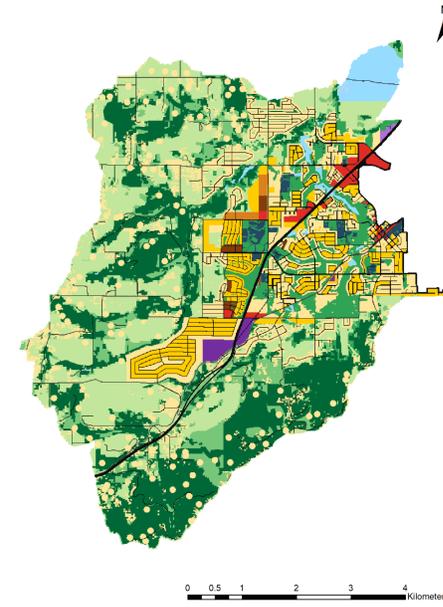

The Early Adopter scenario incorporates all ten key innovations identified as most relevant for our project. The Late Adopter future includes many of the same innovations employed to a lesser extent, while the Non-Adopter scenario illustrates the contrast between futures in which people embrace innovation and those that do not. Sustainable neighborhood pattern and design (#7) incorporates innovations #2-5, #8, #10 at the neighborhood scale. Resilient landscape infrastructure (#2) can be expressed at all scales, whereas #1, #6, and #9 are most relevant at the basin and watershed scale, though they also embody resilient landscape infrastructure.

Example: Green Boulevard Design

- Fewer, smaller parking spaces
- Road width decreases from 12' to 10'; median width increases and trees are planted every 25'

Non-adopter: 2035

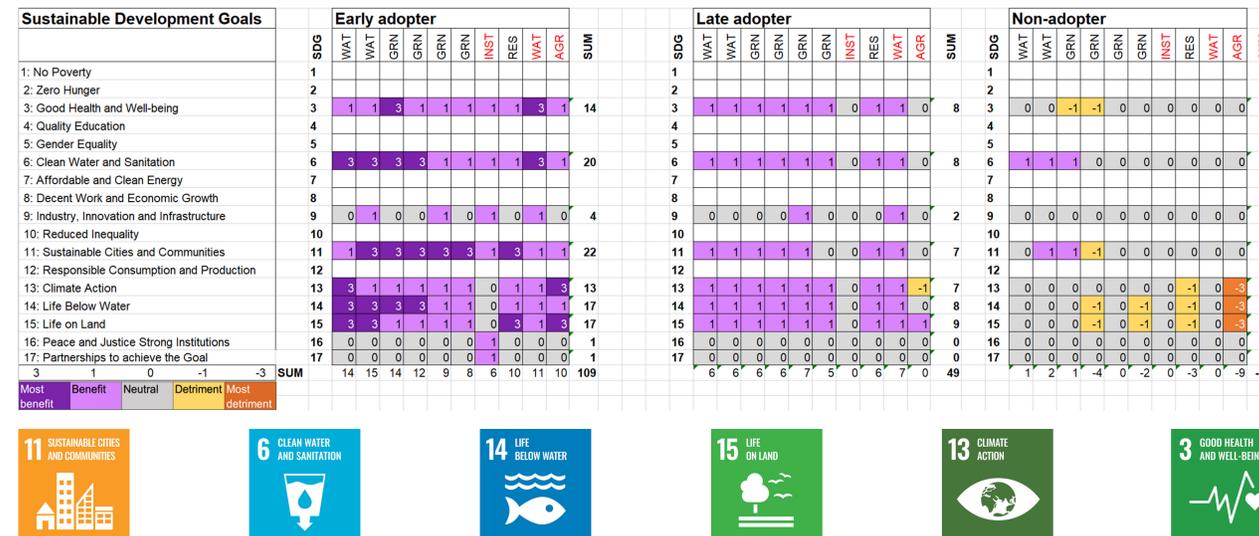

Non-adopter: 2050

Multiple Scales

Impacts to different systems may be important at different scales. For example, increase in impervious area is important at the Neighborhood scale, less so at the Watershed and Basin scale. Impacts of increased forest fire frequency are likely to influence multiple systems and scales.

Findings to Date

The design and modeling of multiscale alternative futures helps stakeholders articulate and visualize how "One Water" management might look in their watershed and neighborhood. Anticipatory efforts can reduce pressures on urban water systems and the environment, but cannot eliminate the challenges created by climate change and population growth.

Non-adopter scenario

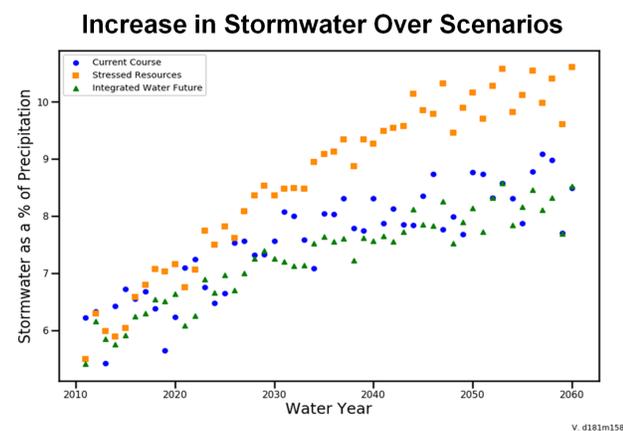

The Oregon Urban Water Innovation Network Stressed Resources ca. 2060 Scenario Narrative Stakeholders advising the project defined the central organizing principle of the SR future as a future in which options are limited by available resources and policies, a "run-to-fail" mindset; as a result, "Water treatment and conveyance infrastructure are stressed." Thus, drinking water supply and quality, stormwater and wastewater facility development, monitoring, and maintenance decline over time.

Development	Watershed Protection	Conservation & Water Re-use	Green Infrastructure
6107 new dwellings; lower density development	Minimal collaboration & little protection of riparian areas; focus on gray infrastructure	Moderate efficiency of water use; little water reuse	Minimal buffers and bioretention areas; 16 ha GI in Sherwood Urban Reserve

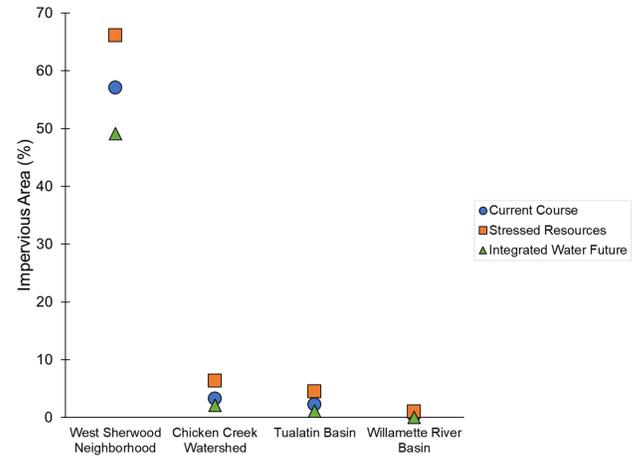

Sustainable Development Goals

This project is most effective in addressing the sustainable development goals (SDG) of Sustainable Cities and Communities (11), Clean Water and Sanitation (6), Life Below Water (14), Life on Land (15), Climate Action (13), and Good Health and Well-being (3). This project defines Stressed Resources as a Non-Adopter scenario and Integrated Water Future as an Early Adopter scenario. Some innovations for SDG exist in only one scenario, their impacts in others are in opposite directions. For example, fuel load reductions for the SDG of climate action (row 13). In the Stressed Resources scenario, climate change combined with inaction will lead to more wildfire, releasing more greenhouse gases which will make climate change worse. However, in an Integrated Water Future scenario, efforts to reduce fuel loads will result in smaller, less frequent fires and lower emissions making this scenario most beneficial.
